

Each column of the heat map is a stage mean of the preprocessed feature; the clock value of that stage is that column weighted by the clock coefficients and summed. Rows are ordered by their contribution to the early-to-late two-cell change, which is $-0.19 = -1.55$ (down) $+1.36$ (up). The remaining 927 of the 1,839 weighted clock genes are not detected in this dataset; they are median-imputed by the clock pipeline, contribute nothing to any difference, and are not plotted.
