

a

(b) Sashimi plots of the late two-cell libraries. Filled area, mean read depth per library of the arm, on one scale per event. Arcs, splice junctions: the number is unique junction reads averaged over the libraries of the arm and the arc width scales with it. The two lower arcs include the alternative exon, the upper arc skips it.

Events chosen by the frozen rule: the three control-activated skipped exons with the largest $|\Delta\text{PSI}|$ that pass the junction depth rule in every library.
